

EFFECT OF POINT SOURCE CONTROL
ON
PHOSPHORUS LOADS TO THE CHESAPEAKE BAY

Prepared for

THE SOAP AND DETERGENT ASSOCIATION
New York, NY

January, 1985

By
Wu-Seng Lung, PhD, PE
Consulting Environmental Engineer
Charlottesville, VA

1. Introduction

Eutrophication is considered the major concern of the Chesapeake Bay due to nutrient enrichment from both point and nonpoint sources in the basin. Several point source control alternatives are being contemplated for the Bay. In order to evaluate the water quality impact (i.e., reduction of eutrophication), we need to determine, as a first step, the reduction of phosphorus loads to the Bay associated with each control alternative. That is, we need to quantify the reduced phosphorus loads discharged from the publicly owned treatment works (POTWs) as well as the reduced loads to the Bay. Further, we put this issue into a better perspective by comparing the reduced point source loads under various control alternatives with the nonpoint source loads from the Bay drainage area.

The results of such an analysis can then be used to assess the water quality improvement, if any, resulting from these control measures. Such water quality impact analysis will, in most cases, require a water quality model to predict the impact. A separate study is being conducted to assess the water quality impact in the James River Estuary in Virginia under various control alternatives. Thus, the results from this study of reduced loads will provide input to the ongoing James River Estuary modeling study.

2. Phosphorus Load Reduction Alternatives

The phosphorus load reduction alternatives evaluated in this study are:

Alt. 1 - basinwide phosphate detergent bans,

Alt. 2 - broadly applied effluent phosphorus limit (2 mg/l) to the POTWs with flows 1 mgd or greater,

Alt. 3 - broadly applied effluent phosphorus limit (2 mg/l) to the POTWs with flows 0.5 mgd or greater,

Alt. 4 - broadly applied effluent phosphorus limit (1 mg/l) to the POTWs with flows 1 mgd or greater, and

Alt. 5 - broadly applied effluent phosphorus limit (1 mg/l) to the POTWs with flows 0.5 mgd or greater.

The basis used for comparison with the control scenarios in terms of load reduction is the 1983 POTW phosphorus loads (Lung, 1984a). In calculating the reduced POTW loads, the 1983 wastewater flows are used. In addition, the default effluent phosphorus concentration of 5 mg/l (Lung, 1984a) is used for the POTWs which do not remove phosphorus and do not measure the effluent phosphorus concentrations.

When considering the phosphate detergent ban alternative, average values of 15% and 25% are used to represent the range of the phosphorus contribution from laundry detergent. Thus, under the phosphate detergent ban alternative, two different load reductions (15% and 25%) are assumed for the POTWs which do not have phosphorus removal. On the other hand, such bans will not have any impact on the POTWs currently practicing phosphorus removal and meeting their current NPDES permit limits.

In calculating the loads associated with the broadly applied effluent limits of 1 mg/l and 2 mg/l, if a POTW already achieves a lower limit, this lower limit applies to the load calculation. For example, the Upper Occoquan AWT in the Potomac River basin had an annual average effluent phosphorus level of 0.028 mg/l. The 1 mg/l or 2 mg/l limit will not have any impact on the phosphorus load calculation for the Upper Occoquan AWT.

3. POTW Phosphorus Load Reduction

The phosphorus loads from the POTWs with wastewater flows greater than 1 mgd under the control alternatives of phosphate detergent bans, 2 mg/l and 1 mg/l effluent phosphorus concentrations are summarized in a number of tables in the Appendix. Also shown in the appendisized tables are the 1983 average loads from Lung (1984a) for comparison purpose. In addition, the 1983 wastewater flows are given along with the 1983 phosphorus concentrations. The phosphorus concentrations resulting from basin-wide

phosphate detergent bans are also presented. Note that a 15% reduction and a 25% reduction in phosphorus concentrations and in phosphorus loads are shown for the POTWs not having phosphorus removal. At the end of each table, an overall phosphorus load reduction is calculated for each of the control alternatives when compared with the 1983 loads. Table 1 summarizes the load reduction estimates for the POTWs in the major river basins tributary to the Bay.

Table 1. Percent (%) Reduction* of POTW Phosphorus Loads
in Major River Basins of the Chesapeake Bay

River Basin	P-Bans			
	(15%)	(25%)	2 mg/l	1 mg/l
Susquehanna:				
upper	15	25	65	83
lower	10	16	42	66
Potomac	7	12	51	65
James	15	25	63	81
Western Chesapeake and Upper Bay	14	23	47	70
Eastern Shore	15	25	60	80
Patuxent	6	10	26	62
Rappahannock	12	20	50	75
York	15	25	60	80

*compared with 1983 POTW loads (Lung, 1984a)

Loads from the plants, not to the Bay

Table 1 shows that several river basins, which do not have phosphorus removal, can achieve the maximum load reductions of 15% and 25% under the phosphate detergent ban scenario. They include the upper Susquehanna, Eastern Shore, York, and James River basins. On the other hand, the Potomac River basin which has many POTWs practicing phosphorus removal would have load reductions ranging from 7% to 12% resulting from the bans.

A 2 mg/l phosphorus limit would result in significant load reductions for the major river basins ranging from 26% in the Patuxent basin to 65% in the upper Susquehanna basin. Similarly, a 1 mg/l phosphorus limit would further reduce the loads. The load reductions for this scenario range from 62% in the Patuxent basin to 83% in the upper Susquehanna basin.

4. Reduction of Phosphorus Loads to the Chesapeake Bay

Following the procedure used by Lung (1984b), the reduced point source phosphorus loads are then incorporated with nonpoint source loads from the Bay watershed to form the total loads entering the Bay. Subsequently, the reductions of the total loads to the Bay attributable to each of the major river basins are summarized in Table 2. The percent reductions associated with three (3) different hydrologic conditions in the Bay drainage basin are shown in Table 2. The different hydrologic conditions are dry year, average year, and wet year conditions (Lung, 1984b). As expected, the percent contributions from point sources in each basin decrease progressively from a dry year to a wet year, so do the percent reductions of loads (see Table 2).

The results in Table 2 indicate that basin-wide phosphate detergent bans would result in small reductions in phosphorus loads to the Bay, ranging from 4.34% in a wet year to 7.36% in a dry year, assuming 15% of the phosphorus in wastewaters from laundry detergent. Similarly, the load reductions range from 7.25% in wet year to 12.3% in a dry year, assuming 25% of the phosphorus from laundry detergent. Such small reductions would be easily compensated by the increase of nonpoint source loads in a wet year. That is, the total phosphorus loads (under phosphate detergent bans) entering the Bay (in lbs/day) in a wet year would still be far greater than those in a dry year (even without bans). The load reductions associated with the broadly applied effluent phosphorus limits of 2 mg/l and 1 mg/l are substantially greater than the reductions due to the phosphate detergent bans. The maximum benefit from phosphorus removal is to be expected in a dry year when the reduction of loads to the Bay would reach over 40%, resulting from the 1 mg/l effluent limit.

Table 2. Percent (%) Reductions of Phosphorus Loads to Chesapeake Bay Resulting from Point Source Control

River Basin	Dry Year				Average Year				Wet Year			
	[15%] P Bans	[25%]	[2mg/l]	[1mg/l]	[15%] P Bans	[25%]	[2mg/l]	[1mg/l]	[15%] P Bans	[25%]	[2mg/l]	[1mg/l]
Susquehanna	0.41	0.68	1.80	2.48	0.30	0.52	1.33	1.83	0.18	0.30	0.80	1.10
Potomac	0.35	0.60	2.55	3.25	0.29	0.49	2.09	2.67	0.18	0.30	1.28	1.63
James	4.35	7.25	18.3	23.5	3.80	6.33	15.9	20.5	2.00	3.33	8.38	10.8
W. Chspk/U. Bay	2.00	3.36	6.86	10.2	1.86	3.13	6.39	9.52	1.82	3.06	6.25	9.31
Eastern Shore	0.16	0.28	0.66	0.88	0.14	0.23	0.54	0.72	0.08	0.13	0.30	0.40
Patuxent	0.05	0.09	0.23	1.18	0.09	0.18	0.42	0.99	0.05	0.09	0.23	0.56
Rappahannock	0.02	0.04	0.10	0.15	0.03	0.04	0.10	0.15	0.01	0.02	0.05	0.08
York	0.02	0.04	0.06	0.08	0.02	0.04	0.06	0.08	0.02	0.04	0.06	0.08
Total	7.36	12.3	30.6	41.7	6.53	10.9	26.9	36.5	4.34	7.25	17.4	23.9

Among all the basins evaluated, the James would benefit the most from these control measures in terms of load reduction simply because the James River basin does not have any phosphorus removal facilities and the POTWs in the James River basin contribute a sizable amount of phosphorus (29% in a dry year) to the Bay (Lung, 1984b).

5. Load Reductions from POTWs with Flows Less Than 1 mgd

The phosphorus loads from the POTWs which have flows under 1 mgd represent only a small portion (6%) of the total POTW phosphorus loads in the basin (Lung, 1984a). These facilities, because of their small size, usually do not have phosphorus removal. Based on the above discussions, the phosphate detergent bans and other phosphorus limits (2 mg/l and 1 mg/l), if applied to these small plants, are not expected to generate significant additional reductions in loads to the Bay.

6. Summary and Conclusions

This study evaluated a number of point source control alternatives which could be used to reduce the phosphorus loads to the Chesapeake Bay. Among the control measures evaluated, phosphate detergent bans were found to have a very small impact on the loads when comparing the reduced loads with existing loads. In fact, the percent reduction resulting from phosphate detergent bans is so small that it can easily be offset by the increase of nonpoint source loads in a wet year. This result implies that nonpoint source control should be considered concurrently with point source control if any appreciable reduction of phosphorus loads to the Bay is to be expected.
